# Gold’s Safe Haven Narrative is Broken — Interest Rates Now Dominate

# Viewpoint

- The traditional narrative of gold price rallying when the geopolitical conflict intensifies doesn’t apply to current situation

- The interest rate expectation is the key to the gold price

- Gold price will stay low as long as the market expects an interest rate hike

# Market observation

- Gold price test record-high when the middle east conflict just started
- The price dropped over 15% within four days as the market increased its expectation on the interest rate
- The market experienced high volatility when the conflict intensifies

# Evidence - Long Term Regime

- In the long-term regime, a 1pp rise in interest rates is associated with a 0.37% decline in gold returns
- The relationship is statistically insignificant ($p=0.267$), suggesting interest rates are not the dominant driver over the full sample
- The low $R^2$ (0.081) suggests that oil, USD, and interest rate movements collectively explain only 8% of gold return variance in the long run, implying the presence of additional drivers
- Additional drivers may include central bank gold purchases, geopolitical risk premia, and retail demand from emerging markets such as China and India

# Evidence - Recent regime

# Evidence - Recent regime

- In the recent regime (2021–present), a 1pp rise in interest rates is associated with a 5.74% decline in monthly gold returns (p=0.001), a relationship that is highly statistically significant.

- Interest rates, USD, and oil have become meaningfully more important drivers of gold in the current rate cycle ($R^2$ = 0.08 ⟶ 0.286) — though roughly 70% of variance remains unexplained, consistent with gold being influenced by multiple factors.

- The interest rate coefficient amplified 15x (coef = -0.004, p = 0.267 ⟶ coef = -0.057, p = 0.001), indicating a structural shift in the gold-rate relationship and the rising dominance of interest rate expectations as a driver of gold price.

# Market pricing

- Market appears to underprice the persistence of high inflation and higher-for-longer rates

Sourced from Federal Reserve Board

- The expected PCE inflation maintains current level through 2026 despite the oil supply shock

# Market pricing

- Despite persistent inflation signals, market pricing still implies partial easing — creating downside risk for gold

- This mispricing creates asymmetric downside risk for gold

Sourced from Federal Reserve Board

# Risk to our view

- Key risk: a collapse in rate expectations ⟶ invalidate the short-gold thesis

# Trading recommendation — Setup

- View: Short gold on rallies toward resistance
- Edge: Market underestimates the persistence of the oil supply shock and Fed's contractionary policy
- Catalyst:
  CPI or PCE > Expectation & Unemployment rate remains strong
  Fed's dot plot shifts upward
- Positioning: Gold positioning crowded on long side, making gold vulnerable to sharp liquidation if rate expectations reprice higher

# Trading recommendation — Execution

- Instrument: Short GC future or Buy GLD put when gold price reach $4950
- Entry Signal: Enter short when gold retraces toward $4,950–$5,000 resistance, confirmed by rising 10Y Treasury yield or hawkish Fed Funds Dot Plot
- Exit/Stop-Loss: Cover if gold breaks back above $5,000 or if Fed signals pivot
- Time Horizon: 1 — 3 months, conditional on inflation and policy data

# Conclusion

- Unless the rate expectation collapses and substantially declines, gold rallies are likely to fade, reinforcing a **sell-on-strength** strategy
